Hibernate

Inheritance: Mapped Super Class

Mapped Super Class

- The annotation `@MappedSuperClass` does not provide a strategy for inheritance.
 - Rather it is a strategy for code re-use
 - With it inheritance only exists in the object model
- Generated Tables are similar to Table Per Class with an abstract super class

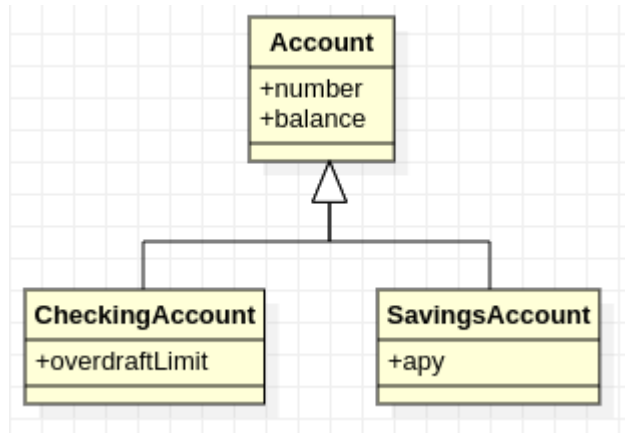

Super Class is not an Entity

No @Entity annotation

```
@MappedSuperClass
public abstract class Account {
    @Id
    @GeneratedValue
    private Long number;
    private double balance;
}
```

```
@Entity
public class SavingsAccount extends Account {
    private double APY;
}
```

```
@Entity
public class CheckingAccount extends Account {
    private double overdraftLimit;
}
```

No Polymorphic Queries

- As the super class is not an entity
 - There is no inheritance in the data model
 - Just 2 entities that happen to share common parts
 - It is **impossible to do polymorphic** queries
- Trying to do so generates an exception
 - QuerySyntaxException: Account is not mapped

Dubious Use

- It is not good to use inheritance for code reuse
- Having inheritance in the object model but not in the data model is strange
 - The point of mapping is to remove differences
- Therefore I recommend to **avoid using** the `@MappedSuperClass` annotation
